1. Flexbox is suitable for linear row/column data. CSS grid is better for a bigger, more complex layout. In CSS, you have a grid format for items to be placed on it, but for Flexbox, everything happens in one direction. They both provide layouts that can be adjusted based on screen size and are generally used for creating a layout for web design.
2. A responsive design means that the web design is designed to adapt to different screen sizes. For instance, the web design would be able to adjust to a mobile device's screen or a laptop screen. A responsive design is more user-friendly because it makes your website accessible to anyone on any device.
